Generating
Playlist

Conclusion
and Future
Work

- Playlist is a sequence of songs which can be created manually by users or automatically by application
- Some online cloud-based services like Spotify allow users to access millions of songs
- Company like Apple have developed algorithms to help generate playlist automatically

Topic

We present Latent Markov Embedding algorithm for generating coherent playlist.

Problem Definition

Generating
Playlist

Conclusion
and Future
Work

- Playlist Prediction: give e seed or a part of playlist what should be the following sequence of songs in order to naturally reflect manually constructed playlist
- The goal of algorithms is to make the generated playlist coherent
- A coherent playlist is defined by a Markov Chain with transition probabilities reflecting similarity of songs

Work

Provide an algorithm named Logistic Markov Embedding

- Models the sequential nature of playlists
- Models playlist as a Markov Chain but not rely on semantic information of songs(genre, emotion, instrument ...)
- Represents songs in Euclidean space

Markov Chain Model of Playlist - I

Goal

The goal is to estimate a generate model of coherent playlist, enable to efficiently sample new playlists

Procedure

Given a connection of songs S_i :

$$S = \{s_1, \dots, s_{|S|}\}$$

we would like to estimate the distribution $Pr(p)$ of coherent playlist $p = (p^{[1]}, \dots, p^{[K_p]})$

- k_p is the length of playlist
- $p^{[i]}$ is one song from S

Markov Chain

- Stochastic process
- Satisfies the Markov property:

$$P(X_n = x_n \mid X_{n-1} = x_{n-1}, \dots, X_0 = x_0) =$$

$$P(X_n = x_n \mid X_{n-1} = x_{n-1})$$

Generating
Playlist

Conclusion
and Future
Work

LME models playlist as paths through a latent space

- Songs are embedded as point or multiple points in this space
- Euclidean distance between songs reflects the transition probabilities
- The key learning problem is to determinate the location of each song using existing playlist as training data

Single Point Model - I

Work

Space representation

Represent each song as a single vector $X(s)$ in d-dimensional Euclidean space

Transition probability

$$Pr(p^{[i]} \mid p^{[i-1]}) = \frac{e^{\|X(p^{[i]}) - X(p^{[i-1]})\|_2^2}}{\sum_{j=1}^{|S|} e^{\|X(s_j) - X(p^{[i-1]})\|_2^2}}$$

Single Point Model - II

Generating
Playlist

Conclusion
and Future
Work

If we write:

$$Z(p^{[i-1]}) = \sum_{j=1}^{|S|} e^{\|X(s_j) - X(p^{[i-1]})\|_2^2}$$

$$\Delta(s, s') = \|X(s) - X(s')\|_2$$

Probability of a playlist p :

$$Pr(p) = \prod_{i=1}^{k_p} Pr(p^{[i]} \mid p^{[i-1]}) = \prod_{i=1}^{k_p} \frac{e^{-\Delta(p^{[i]}, p^{[i-1]})^2}}{Z(p^{[i-1]})}$$

Model Regularization - I

Experiment
and
Evaluation

Generating
Playlist

Conclusion
and Future
Work

- X : latent representation of songs
- Introduce the norm-based regularizers by penalizing the Frobenius norm of $X \in R^{|S| \times d}$

$$X = \operatorname{argmax}_{X \in R^{|S| \times d}} L(D | X) - \lambda \|X\|_F^2$$

- For increasing values of λ , this regularizer encourages vectors to stay close to the origin

Experiment
and
Evaluation

Generating
Playlist

Conclusion
and Future
Work

- Calculate a matrix T where $T_{a,b}$ are number of transitions from song s_a to s_b in the training set
- Get a equivalent model

$$L(D | X) = \sum_{a=1}^{|S|} \sum_{b=1}^{|S|} T_{a,b} l(s_a, s_b) - \Omega(X)$$

- Use stochastic gradient training to get the best location of all songs in the training data

Playlist

Conclusion
and Future
Work

Computational cost

$O(|S|^2)$ running time is too slow in practical applications

- Do not need to consider all the transitions from current s_i to all the song in S
- Most songs are not likely targets to transit

Landmark heuristic method

only consider a subset C_i^r as possible successors for s_i where r is the percent of the total songs

$$L(D \mid X) = \sum_{a=1}^{|S|} \sum_{s_b \in C_a^r} T_{a,b} I(s_a, s_b) - \Omega(X)$$

What is embedding look like?

Dataset

Crawled playlist from Yes.com from Dec 2010 to May 2011 by using its API

set	Quantity
Number of song	3168
Number of Train Transitions	134.431
Number of Test Transition	1.191.279

Evaluation

Compare the performance of LME versus bigram using as metric the average log-likelihood as metric:

$$\log(Pr(D_{test}))/N_{test}$$

LME vs Bigram

Bigram Model

- Also a first-order Markov Chain
- Transition probabilities $p(s_j | s_i)$ are estimated for every pair of songs by calculating the number of appearances

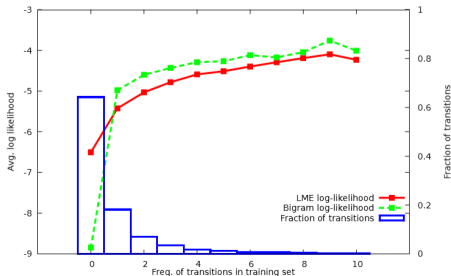

Figure 2: Log likelihood on testing transitions with respect to their frequencies in the training set

Capture Coherency of Playlist?

Introduction

Playlist
Prediction
Problems

Metric
Model of
Playlist

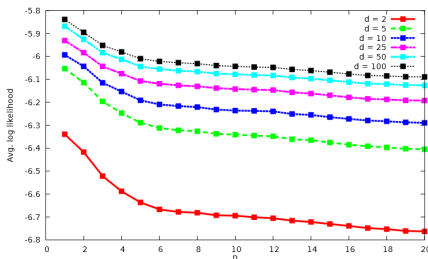

Solve Model
Optimization
Problem

Experiment
and
Evaluation

Generating
Playlist

Conclusion
and Future
Work

- Build the model on the 1-hop transition in the training dataset
- The test is done on the n -hop transitions in the test dataset

- Song that are sequentially to each other in the playlist are more likely to form a transition pair

How to Generate a Playlist?

and
Evaluation

Generating
Playlist

Conclusion
and Future
Work

Steps

- Given a seed location (a song) in the Euclidean Space
- Repeatedly sample songs from the transition distribution

Problem

The average model represents an average model of playlist but each user may have different preferences

Extending the model

Generating
Playlist

Conclusion
and Future
Work

Basic LME models can be extended in a variety of ways

- Have only limited means of expressing the popularity of a song
- Add a separate "popularity boost" b_i to song s_i

$$Pr(p^{[i]} | p^{[i-1]}) = \frac{e^{-\Delta(p^{[i]}, p^{[i-1]})^2 + b_i}}{\sum_j e^{-\Delta(s_j, p^{[i-1]})^2 + b_j}}$$

- Other extending: user preference, semantic information
